Motivation for computer scientists

- Convenient language: (Higher) category theory is a very general organizational principle for mathematics. Sometimes one notices that the same construction appears in multiple contexts. Category theory allows you to formalize this via universal constructions. Most of modern mathematics¹ is written in the language of category theory.
- Compositionality. Sometimes one wants to break a program down into smaller parts that can each be analysed independently.
- Logic. There is a correspondence with logic via the Curry-Howard correspondence. Take Henning's course during master for more!

¹or at least algebra and topology since the 1960s

- Concrete applications
 - Functional programming: Category theory underlies the theory and syntax of functional programming languages such as OCaml and Haskell.
 - **② Linguistics:** Category theory has been used to study human language.
 - Processes in CS: To analyse all manner of processes in CS; from optimization algorithms to attack trees.

Direct sum of vector spaces

Given two vector spaces you can construct their direct sum:

Definition

Given two vector spaces V, W the direct sum is defined as:

$$V \oplus W = \{(v, w) \mid v \in V, w \in W\}$$

To define the vector space structure

$$(v_1, w_1) + (v_2, w_2) = (v_1 + v_2, w_1 + v_2)$$
 $v_1, v_2 \in V, w_1, w_2 \in W$
 $\lambda \cdot (v, w) = (\lambda v, \lambda w)$

There are canonical inclusions

$$i_V: V \to V \oplus W, \qquad v \mapsto (v,0)$$

$$i_V: W \to V \oplus W \qquad w \mapsto (0, w)$$

Disadvantages of this definition

- Rather ad hoc and messy. Need to define the vector space structure by hand.
- Hides the role of the canonical inclusions.
- Doesn't generalise well.

Universal constructions: Direct sum of vector spaces

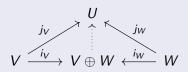

You saw the direct product of vector spaces two weeks ago. But there is a different way to construct it:

Definition

Given two vector spaces V, W the direct product is defined to be the **unique** vector space $V \oplus W$ equipped with maps $i_V : V \to V \oplus W$ and $i_W : W \to V \oplus W$ such that for any vector space U, with maps $j_V : V \to U$ and $j_W : W \to U$ there is a unique map

$$V \oplus W \rightarrow U$$

making the following diagram commute:

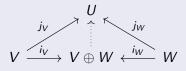

Universal constructions: Coproducts

Definition

Given two vector spaces V, W the direct product is defined to be the **unique** vector space $V \oplus W$ equipped with maps $i_V : V \to V \oplus W$ and $i_W : W \to V \oplus W$ such that for any vector space U, with maps $j_V : V \to U$ and $j_W : W \to U$ there is a unique map

$$V \oplus W \rightarrow U$$

making the following diagram commute:

This is an example of a very general construction: the **categorical coproduct.**

Data of a category

Definition

A category C consists of

- lacktriangle a class of **objects** ob $\mathcal C$
- ② for any two objects $A, B \in \mathcal{C}$ a class of **morphisms** $\mathsf{Hom}(A, B)$
- **③** For any three objects $A, B, C \in \text{ob } \mathcal{C}$, a binary operation called **composition**

$$\circ_{A,B,C}: \mathsf{Hom}(A,B) imes \mathsf{Hom}(B,C) o \mathsf{Hom}(A,C)$$
 $(f,g) \mapsto g \circ f$

Axioms of composition

Composition is supposed to model function composition. This boils down to the following two axioms.

• The operation \circ is associative. In other words, if $h: A \to B$, $g: B \to C$ and $f: C \to D$ for $A, B, C, D \in ob(C)$, we have that:

$$(f \circ g) \circ h = f \circ (g \circ h)$$

as a function from $A \rightarrow D$.

• For $A \in ob(\mathcal{C})$, the hom-class Hom(A, A) contains an identity element $id_A : A \to A$, such that for any $f : A \to B$, we have

$$id_A \circ f = f = f \circ id_A$$

Category of sets

Proposition

Consider the class of sets. For any two sets A, B, let

$$Hom(A, B) = \{f : A \rightarrow B \mid f \text{ is a function.}\}\$$

Composition is defined by function composition. This defines a category **Set**.

Category of pointed sets

Proposition

Consider the class of non-empty sets (A, a_0) with one distingushed element $a_0 \in A$. For any two pointed sets $(A, a_0), (B, b_0)$, define

$$\mathsf{Hom}((A,a_0),(B,b_0)) = \{f:A o B\mid f \ \textit{is a function such that}\ f(a_0)=b_0\}$$

Composition is defined by function composition. This defines a category \mathbf{Set}_{\bullet} .

Many of the mathematical structures that you have seen in previous lectures organize into categories

- Sets and functions. We call this category **Set**.
- Vector spaces and

- Metric spaces and continuous maps (or short maps). We call this category Met.
- Topological spaces and continuous maps. We call this category Top.
 You will encounter it next week.

Universal constructions in a categories

Definition

Let $\mathcal C$ be a category. Given $V,W\in\mathcal C$ the coproduct is defined to be the **unique** (if it exists) $V\coprod W$ equipped with maps $i_V:V\to V\oplus W$ and $i_W:W\to V\oplus W$ such that for $U\in\mathcal C$, with maps $j_V:V\to U$ and $j_W:W\to U$ there is a unique map

$$V \oplus W \rightarrow U$$

making the following diagram commute:

Functors

Given two categories, we can define "functions" between them.

Definition

Let C and D be categories. A functor F consists of a function

$$\mathsf{ob}\,\mathcal{C}\to\mathsf{ob}\,\mathcal{D}$$

$$A \mapsto F(A)$$

along with a map

$$\mathsf{Hom}(A,B) \to \mathsf{Hom}(F(A),F(B))$$

$$f \mapsto F(f)$$

for all $A, B \in \mathcal{C}$

Functors

Given two categories, we can define "functions" between them.

Definition

Let $\mathcal C$ and $\mathcal D$ be categories. A functor F consists of a function

$$\mathsf{ob}\,\mathcal{C} \to \mathsf{ob}\,\mathcal{D}$$

$$A \mapsto F(A)$$

along with a map

$$\operatorname{\mathsf{Hom}}(A,B) \to \operatorname{\mathsf{Hom}}(F(A),F(B))$$

$$f \mapsto F(f)$$

for all $A, B \in \mathcal{C}$. This map should have some properties with respect to composition.

Properties of functors

Functors should preserve the compositional structure of the category. In other words:

- Composition is conserved $F(f \circ g) = F(f) \circ F(g)$ for $g : A \to B$ and $f : B \to C$.
- Identity maps are conserved

$$F(\mathrm{id}_A)=\mathrm{id}_{F(A)}$$

Pointed sets

There is a forgetful functor

$$U:\mathsf{Set}_{ullet} o \mathsf{Set}$$

$$U(A, a_0) = A$$
 and $U(f) = f$.

Examples of functors

There is a forgetful functor

$$|-|: \mathbf{Vect} \to \mathbf{Set}$$
 $X \mapsto |X|.$

It assigns to every vector space its underlying category of points. It assigns to every morphism $f:V\to W$, the map $|f|:|V|\to |W|$, that sends x to f(x). The map **forgets** the fact that X is a vector space.

 Similarly there are forgetful functors from metric, Banach and topological spaces to sets defined in the same way. There are other forgetful functors from Banach to Hilbert spaces, and from metric to topological spaces. You will encounter them on your homework.

Other examples of functors

• There is a free functor

$$\mathbb{R}[-]:$$
 Set o Vect

$$X \mapsto \{f : X \to \mathbb{R} \mid \mathsf{Supp}\, f \text{ is finite.}\}$$
.

where Supp $f = \{x \in X \mid f(x) \neq 0\}$. For example, it sends $\{e_1, e_2\}$ to \mathbb{R}^2 . It sends a map $f : X \to Y$ to the map

$$\mathbb{R}[f]: \mathbb{R}[X] \to \mathbb{R}[Y]$$

$$\sum_{i\in X}a_ix\mapsto\sum_{i\in X}a_if(x)$$

For example, it sends $e_1
ightarrow e_2$ and $e_2
ightarrow e_1$ to the linear map

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} : \mathbb{R}^2 \to \mathbb{R}^2.$$

Dual categories

Given any category C, we can construct its **dual category** C^{op} .

ullet The objects of \mathcal{C}^{op} are the same as \mathcal{C}^{op} . In other words

$$\mathsf{ob}\,\mathcal{C}^{\mathit{op}} = \mathsf{ob}\,\mathcal{C}$$

We have

$$\mathsf{Hom}_{\mathcal{C}^{op}}(A,B) = \mathsf{Hom}_{\mathcal{C}}(B,A)$$

In other words, if there is a map $f:A\to B$ in $\mathcal C$, there is a map $f^{op}:B\to A$.

In fact $(-)^{op}$ is a functor.

The extension functor

Lemma

There is a functor $E: \mathbf{Set} \to \mathbf{Set}_{\bullet}$ and for all $X \in \mathbf{Set}$ a map $i_X: X \to U(EX)$, such that for all $(Y, y_0) \in \mathbf{Set}_{\bullet}$ and all maps $f: X \to U(Y, y_0)$, there exists a **unique** pointed map $\tilde{f}: EX \to (Y, y_0)$ making the following diagram commute:

$$X \xrightarrow{f} Y = U(Y, y_0)$$

$$\downarrow^{i_X} U\tilde{f}$$

$$U(E(X))$$

Question to class

- How do you think you define EX and Ef?
- One definition:

$$EX = (\{\{0\} \cup \{(1, x \mid x \in X)\}, 0)$$

and

$$Ef(u) = \begin{cases} (1, f(x)) & \text{for } u = (1, x) \\ 0 & \text{for } u = 0. \end{cases}$$

Exercises on categories 1

- Oo sets and injective maps form a category? What about sets and strict inclusions?
- ② Consider the set of **bracketed** words on some alphabet $\{e, a_1, a_2, \dots a_n\}$ where, for any word w, we have that we = ew = w. Define

$$\mathsf{Hom}(w_1, w_2) = \{u \mid (w_1)(u) = w_2\}$$

Define $u \circ v = (v)(u)$ Does this form a category? What about **unbracketed** words?

- **3** Show that a vector space V and all linear maps $V \to V$ form a 1-object category.
- **4** A **unital monoid** is a set X equipped with a binary associative operation $X \times X \to X$ that is associative and which has an identity element. Show that there is a one-to-one correspondence between unital monoids and categories with one element.

Exercises on universal constructions

- Is the forgetful functor Vect → Set faithful? Can you obtain every map of sets this way?
- ② What linear transformations are of the form F(f) for $f: X \to Y$ for the free functor $F: \mathsf{Set} \to \mathsf{Vect}$. Hint: Express it in terms of matrices.
